

## RV For Sale Winnipeg

**RV For Sale Winnipeg - Dumping Sites** - A dump site, or station, is the term for the place where RV waste tanks are drained. There would be a flat concrete area which has brass fittings that will accept the sewer hose of the recreational vehicle. These will have a moving lid which would stop debris from falling into the pipes. The tank sewage dumped here will be sanitized and disposed of by the septic tank of the campground. These recreational vehicle dumping stations are made to enable the RV easy access to these receptacles. Additionally, the dump site would supply clean water hoses to wash down the concrete station pad and properly rinse the waste water tanks.

### Dumping Wastewater Tanks

This term describes the method used to empty wastewater tanks. It is really essential to empty the tanks in a particular sequential order. Black water should be dumped first, followed by the gray water. This allows the foamy gray water to wash the black water away that keeps the hose of the recreational vehicle fairly clean.

### Fresh Water Tanks

These would be utilized for storing fresh water whilst traveling. In order to make certain this water remains fresh, it must be emptied regularly. These tanks would come with precise instructions concerning winterizing the RV to ensure this tank and the pipes can be subject to freezing.

### Generator

In a diesel, propane or gas machine, the generator is used to power 240 or 120 volt AC power. This is usually utilized during dry camping. Wattage is the calculation of electrical output from the generator. The larger types of recreational vehicles that utilize a range of air conditioners will need a six thousand wattage generator at the least even if sometimes more power would be needed. A medium sized recreational vehicle will need a bare minimum of 3000 watts and smaller vehicles would use 1500-2000 watts. These generators could also regenerate the house battery system. Though they are not popular in European designed recreational vehicles because of the noise they create but they are usually found in North American RV's.

### Electrical Trailer Brakes

On fifth wheel trailers and vehicles, a secondary system utilized to halt the vehicles is necessary. A 12 volt braking device which is located inside the vehicle cab will provide an electrical current to operate the electrical braking system in the trailer's wheels. With a small pendulum, this system would sense the movements of the vehicle and utilize an electrical current to help stop the recreational vehicle. This current is entirely dependent on how quickly the vehicle is required to stop or slow down.

### Fifth Wheel Coupling

Also referred to as the hitch, the fifth wheel coupling is the link which connects the towing vehicle to the trailer. Fifth wheel hitches today have a two dimensional aspect which makes much easier to connect the two vehicles. This also provides an ease of movement from the trailer to the towing truck. Several RV's would have a hitch called a sliding fifth wheel and this allows the vehicle to reverse more easily in tight spots. This ensures that the trailer does not impact the towing vehicle while making sharp turns.
